

Choosing a statistical test, in the order the questions are asked

Shared by all four projects. Stop at the first 'yes'. Each branch names the narrowest test whose assumption is satisfied.

Two rules override the whole tree

1. Report the effect size, not only the p-value — matched-pairs rank-biserial r for rank tests, Hedges' g for means, Wilson intervals for proportions.
2. Never test a null the design cannot detect — compute the minimum detectable effect at 80% power before running anything.
